Abstract

This paper is concerned with the solution of the nanoscale structures consisting of the *InAs/GaAs* with an effective mass envelope function theory, the electronic states of the *InAs/GaAs* quantum ring are studied. In calculations, the effects due to the different effective masses of electrons in and out the rings are included. The energy levels of the electron are calculated in the different shapes of rings, i.e., that the inner radius of rings sensitively change the electronic states. The energy levels of the electron are not sensitively dependent on the outer radius for large rings. The structures of *InAs/GaAs* quantum rings are studied by the one electronic band Hamiltonian effective mass approximation, the energy- and position-dependent on electron effective mass approximation, and the spin-dependent on the Ben Daniel-Duke boundary conditions. In the description of the Hamiltonian matrix elements, the Finite elements method with different base piecewise linear function is adopted. The non-linear energy confinement problem is solved approximately by using the Finite elements method with piecewise linear function, to calculate the energy of the one electron states for the *InAs/GaAs* quantum ring. The results of numerical example are compared for accuracy and efficiency with the finite element method of linear triangular element. This comparison shows that good results of numerical example.

Keywords: nanoscale, Finite elements method, Ben Daniel-Duke boundary conditions, *InAs/GaAs* quantum rings.

1. Introduction

The modeling of the electron states in semiconductor nanostructures remains a difficult computational task. The one electron states are helpful for studying the electron correlations and, the effects of magnetic fields in quantum rings and useful for designing and fabricating the double colors detector by intra band and inter band translations.

In 1990, Paasch et. al., [3] used envelope equation and wave function matching for narrow-gap semiconductors. In 1995, Mathine et. al., [4] applied computational Fourier series solution of the BenDaniel-Duke Hamiltonian for arbitrary shaped quantum wells. In 2001, Yiming Li et al, [1] used Computer simulation of electron energy levels for different shape *InAs/GaAs* semiconductor quantum dots. In 2002, Yiming Li et al, [2] used Electron energy state spin-splitting in 3D cylindrical semiconductor quantum dots. In 2003, Melnik et al, [5] applied finite element analysis of Nanowire superlattice structures. Whereas 2005, Yiming Li, [6] using an iterative method for single and vertically stacked semiconductor quantum dots simulation. In 2016, Deyasi et. al., [7] applied numerically computed in presence of electric field using propagation matrix method. In 2017, Eman et. al., [8] using finite element method with linear triangular element for solving finite nanowire superlattice quantum dot structures *GaAs/AlGaAs*. In 2017, Eman et. al., [9] using finite element method with linear rectangular element for solving finite nanowire superlattice quantum dot structures *GaAs/AlGaAs* results.

Modeling Energy Stat with Spin-Dependent Boundary Conditions [5 & 6]

We consider the problem to compute relevant energy states and corresponding wave functions of a three dimensional semiconductor quantum ring. Consider the one electrons is confined in system of the three-dimensional quantum ring structures and apply an effective one electronic band Hamiltonian, is given by:

$$\hat{H} = \hat{H}_0 + \hat{V}_{so}(r), \quad (1)$$

where \hat{H} is the Hamiltonian of the system without spin-orbit interaction, $\hat{V}_{so}(r)$ is the spin-orbit interaction for the conduction band electrons, and the expression for \hat{H}_0 is as follows:

$$\hat{H}_0 = -\frac{\hbar^2}{2} \nabla_r \left(\frac{1}{m(E, r)} \right) \nabla_r + V(r) \quad (2)$$

where ∇_r is the spatial gradient, $m(E, r)$ is the energy dependent electron effective mass, and $V(r)$ is the confinement potential.

$$\frac{1}{m(E, r)} = \frac{P^2}{\hbar^2} \left[\frac{2}{E + E_g(r) - V(r)} + \frac{1}{E + E_g(r) + \Delta(r) - V(r)} \right] \quad (3)$$

where $E_g(r)$ and $\Delta(r)$ stand for the position dependent band gap and the spin-orbit splitting in the valence band, respectively and, P is the momentum matrix element..

The spin-orbit interaction for the conduction band electrons $\hat{V}_{so}(r)$ is given by

For more information about the Conference please visit the websites:

<http://www.ihsciconf.org/conf/>

www.ihsciconf.org

$$\hat{V}_{so}(r) = i\nabla\beta(E, r) \cdot [\hat{\sigma} \times \nabla] \quad (4)$$

where $\beta(E, r)$ is the spin-orbit coupling parameter and $\hat{\sigma} = \{\sigma_x, \sigma_y, \sigma_z\}$ is the vector of the Pauli matrices. The energy and position dependent $\beta(E, r)$ has the form

$$\beta(E, r) = \frac{P^2}{2} \left[\frac{1}{E + E_g(r) - V(r)} - \frac{1}{E + E_g(r) + \Delta(r) - V(r)} \right] \quad (5)$$

For those quantum ring systems that have sharp discontinuity on the conduction band interfaces between the quantum ring ("InAs" material 1) and semiconductor matrix ("GaAs" material 2), the hard-wall confinement potential is

$$V(r) = \begin{cases} 0, & r \in \text{material 1} \\ V_0, & r \in \text{material 2,} \end{cases} \quad (6)$$

where V_0 is the structure band offset. Combining the Hamiltonian in equations (1), (2), and (4), the spin dependent Ben Daniel-Duke boundary conditions for the electron wave function $\Psi(r)$ is written as follows:

$$\Psi_{\text{material 1}}(r_s) = \Psi_{\text{material 2}}(r_s) \quad (7)$$

$$\left\{ \frac{\hbar^2}{2m(E, r)} \nabla - i\nabla\beta(E, r)[\hat{\sigma} \times \nabla] \right\}_n \Psi(r_s) = C_0$$

where V_0 is the some constant, r_s denotes the position of the system interface.

Note (1): We note that the expressions of electron effective mass in equation (3), spin-orbit coupling parameter in equation (5), and the equations of Ben Daniel-Duke boundary condition in equation (7) are all energy and position dependent relationships in this study.

2. Finite Element Method

Dependence of the electron effective mass and spin-orbit coupling parameter on each energy state results in a nonlinear equation (9) and (10). The nonlinear equations complicate the process of analytical solution in the explored quantum ring. Therefore, the numerical approach to the solution of the nonlinear equations is advanced in the calculation of the electronic structure of InAs/GaAs quantum rings. The finite element method is applied to solve the above problem for the nanoscale InAs/GaAs quantum rings. Energy states and spin-splitting are numerically calculated without any fitting parameters. Starting from a given initial energy, the finite element method globally calculates all bounded energies for the corresponding nonlinear algebraic eigenvalue problem. A computational procedure of the finite element method is shown below:

$$-\frac{\hbar^2}{2m_i(E)} \left(\frac{\partial^2}{\partial R^2} + \frac{\partial}{R\partial R} + \frac{\partial^2}{\partial Z^2} - \frac{l^2}{R^2} \right) \phi_i(R, Z) + V\phi_i(R, Z) = E\phi_i(R, Z), \quad \forall(R, Z)$$

$$\in \text{material } i \quad (12)$$

Where $i = 1, 2$ since the cylindrical is symmetry, $V = V(R, Z)$, and $\phi_i = u(R, Z)e^{il\phi_i}$, where l is an integer. Equation (12) becomes

For more information about the Conference please visit the websites:

<http://www.ihsciconf.org/conf/>
www.ihsciconf.org

$$\begin{aligned} & \frac{-\hbar^2}{2m_i(E)} \left[\frac{1}{R} \frac{\partial u}{\partial R} + \frac{\partial}{\partial R} \left(\frac{\partial u}{\partial R} \right) - \frac{l^2}{R^2} u + \frac{\partial}{\partial Z} \left(\frac{\partial u}{\partial Z} \right) \right] + Vu \\ & = Eu \end{aligned} \quad (13)$$

The electron energy spectra for *InAs/GaAs* quantum rings the semiconductor band structure governing physical process in a ring nanoscale are described in terms of cylindrical coordinates. When the geometry, loading, and boundary conditions are independent of the circumferential direction (ϕ -coordinate), the electron energy spectra for *InAs/GaAs* quantum rings of the semiconductor band structure equation become two-dimensional in terms of R and Z .

2.1 Weak Form

Assume that Ω is a typical element the piecewise linear function of the finite element mesh, and we develop the finite element model of equation (13) over Ω . Various two-dimensional elements will be discussed in the sequel.

There are three steps in the development of the weak form of equation (13) over the typical element Ω .

The first step is formulated equation (13) by the following weak form.

$$\begin{aligned} & 0 \\ & = \int_{\Omega} \left[\frac{-\hbar^2}{2} \left[w \frac{1}{m_i(E)} \frac{\partial u}{\partial R} + wR \frac{\partial F_1}{\partial R} - \frac{l^2}{m_i(E)R} wu + wR \frac{\partial F_2}{\partial Z} \right] + VwRu \right. \\ & \quad \left. - EwRu \right] dRdZ \end{aligned} \quad (12)$$

Where

$$F_1 = \left(\frac{1}{m_i(E)} \frac{\partial u}{\partial R} \right) \quad \text{and} \quad F_2 = \left(\frac{1}{m_i(E)} \frac{\partial u}{\partial Z} \right)$$

In the second step, we note the identities

$$\begin{aligned} -wR \frac{\partial F_1}{\partial R} &= R \frac{\partial w}{\partial R} F_1 \\ &\quad - R \frac{\partial}{\partial R} (wF_1) \end{aligned} \quad (15a)$$

$$\begin{aligned} -wR \frac{\partial F_2}{\partial Z} &= R \frac{\partial w}{\partial Z} F_2 \\ &\quad - R \frac{\partial}{\partial Z} (wF_2) \end{aligned} \quad (15b)$$

Next, using equation (15a) and equation (15b) in the equation (14) then applying the divergence theorem, we obtain

For more information about the Conference please visit the websites:

<http://www.ihsciconf.org/conf/>
www.ihsciconf.org

$$\begin{aligned}
0 = \int_{\Omega} \left[\frac{-\hbar^2}{2m_i} w \frac{\partial u}{\partial R} + \frac{\hbar^2}{2} R \frac{\partial w}{\partial R} \left(\frac{1}{m_i} \frac{\partial u}{\partial R} \right) + \frac{\hbar^2 L^2}{2m_i R} w u + \frac{\hbar^2}{2} R \frac{\partial w}{\partial Z} \left(\frac{1}{m_i} \frac{\partial u}{\partial Z} \right) + w R V u \right. \\
\left. - w R E u \right] dR dZ \\
- \oint_{\Gamma} w \left[n_1 \left(\frac{1}{m_i} \frac{\partial u}{\partial Z} \right) + n_2 \left(\frac{R}{m_i} \frac{\partial u}{\partial R} \right) \right] ds \quad (16)
\end{aligned}$$

where $\vec{n} = (n_1, n_2)$ is an outer unit vector normal on Γ and ds is the length of an infinitesimal line element along the boundary.

From an inspection of the boundary integral in (16), we note that the specification of u constitutes the essential boundary condition, and hence u is the primary variable. The specification of the coefficient of the weight function in the boundary expression, i.e. we can let

$$\begin{aligned}
d_n \equiv n_1 \left(\frac{1}{m_i} \frac{\partial u}{\partial Z} \right) \\
+ n_2 \left(\frac{R}{m_i} \frac{\partial u}{\partial R} \right) \quad (17)
\end{aligned}$$

The third and last step of the formulation is to substitute the definition (17) in (16) and write the weak form of (13) as

$$\begin{aligned}
0 = \int_{\Omega} \left[\frac{-\hbar^2}{2m_i} w \frac{\partial u}{\partial R} + \frac{\hbar^2}{2} R \frac{\partial w}{\partial R} \left(\frac{1}{m_i} \frac{\partial u}{\partial R} \right) + \frac{\hbar^2 L^2}{2m_i R} w u + \frac{\hbar^2}{2} r \frac{\partial w}{\partial Z} \left(\frac{1}{m_i} \frac{\partial u}{\partial Z} \right) + w r V u \right. \\
\left. - w r E u \right] dR dZ \\
- \oint_{\Gamma} w d_n ds \quad (18)
\end{aligned}$$

Now, $u(R, Z)$ is approximated over a typical finite element Ω by the expression

$$\begin{aligned}
u(R, Z) \approx u_h^e(R, Z) \\
= \sum_{j=1}^n u_j^e \psi_j^e(R, Z) \quad (19)
\end{aligned}$$

where $u_j^e(R, Z)$ is the value of $u_h^e(R, Z)$ at the j^{th} node (R_j, Z_j) of the element. Substituting the finite element approximation (19) for u into the weak form (18), we get

For more information about the Conference please visit the websites:

<http://www.ihsciconf.org/conf/>

www.ihsciconf.org

$$\begin{aligned}
& 0 \\
& = \int_{\Omega} \left[\frac{-\hbar^2}{2m_i} w \sum_{j=1}^n u_j^e \frac{\partial \psi_j^e}{\partial R} + \frac{\hbar^2}{2} R \frac{\partial w}{\partial R} \left(\frac{1}{m_i} \sum_{j=1}^n u_j^e \frac{\partial \psi_j^e}{\partial R} \right) + \frac{\hbar^2 l^2}{2m_i R} w \sum_{j=1}^n u_j^e \psi_j^e \right. \\
& \quad \left. + \frac{\hbar^2}{2} R \frac{\partial w}{\partial Z} \left(\frac{1}{m_i} \sum_{j=1}^n u_j^e \frac{\partial \psi_j^e}{\partial Z} \right) + wRV \sum_{j=1}^n u_j^e \psi_j^e - wRE \sum_{j=1}^n u_j^e \psi_j^e \right] dRdZ \\
& \quad - \oint_{\Gamma} w d_n ds \tag{20}
\end{aligned}$$

This equation must hold for every admissible choice of weight function w . Since we need n independent algebraic equations to solve for the n unknowns, $u_1^e, u_2^e, \dots, u_n^e$, we choose n linearly independent functions for w : $w = \psi_1^e, \psi_2^e, \dots, \psi_n^e$. For each choice of w we obtain an algebraic relation among $(u_1^e, u_2^e, \dots, u_n^e)$. We label the algebraic equation resulting from substitution of $w = \psi_i^e$ into (20):

$$\begin{aligned}
0 = \sum_{j=1}^n \left\{ \int_{\Omega} \left[\frac{-\hbar^2}{2m_i} \psi_i^e \frac{\partial \psi_j^e}{\partial R} + \frac{\hbar^2}{2} R \frac{\partial \psi_i^e}{\partial R} \left(\frac{1}{m_i} \frac{\partial \psi_j^e}{\partial R} \right) + \frac{\hbar^2 L^2}{2m_i R} \psi_i^e \psi_j^e + \frac{\hbar^2}{2} R \frac{\partial \psi_i^e}{\partial Z} \left(\frac{1}{m_i} \frac{\partial \psi_j^e}{\partial Z} \right) \right. \right. \\
\quad \left. \left. + RV \psi_i^e \psi_j^e - RE \psi_i^e \psi_j^e \right] dRdZ \right\} u_j^e - \oint_{\Gamma} w d_n ds; \quad i, j \\
= 1, 2, \dots, n \tag{21}
\end{aligned}$$

2.2 Finite Element Method for the Model with Piecewise Linear Functions

In this section, the solution u of equation (18) is approximated by a FEM for the model with piecewise linear function.

We now define V_h as follows:

$$V_h = \{v: v \text{ is continuous on } \Omega, v = 0 \text{ on } \Gamma\}.$$

The space V_h consists of all continuous function that are linear on each triangle K and vanish on Γ . We notice that $V_h \subset V$. As parameters to describe a function $v \in V_h$ we choose the values $v(N_i)$ of v at the nodes $N_i, i = 1, \dots, N$, of T_h but exclude the nodes on the boundary since $v = 0$ on Γ .

The corresponding basis function $\varphi_j \in V_h, j = 1, \dots, N$, are then defined by (see Figure(2))

$$\varphi_j(N_j) = \delta_{ij} \equiv \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases} \quad i, j = 1, \dots, M.$$

The finite element method was applied to project the variational form of the problem onto a finite dimensional space. As a result, the problem was reduced to the following generalized eigenvalue problem:

$$\begin{aligned}
Au \\
= \lambda B \tag{22}
\end{aligned}$$

where A and B are $N \times N$ matrices, u the vector of unknowns of dimensionality N , and N the number of nodes in which the solution to the problem (13) is being sought. Computational domains of interest are symmetric with respect to the z -axis, where we imposed Neumann's boundary conditions if $L = 0$. The solution to equation (22) was found in MATLAB.

For more information about the Conference please visit the websites:

<http://www.ihsciconf.org/conf/>

www.ihsciconf.org

We employed the finite element method so as to calculate electron eigenvalues and eigenstates for a series of finite NWSL structures with a cylindrical cross-section. In this case the matrices in equation (22) has the following form

where

$A = [A_{ij}]$ and $B = [B_{ij}], i = 1, 2, \dots, N, j = 1, 2, \dots, N.$

$$A_{ij} = \int_{\Omega} \left[\frac{-\hbar^2}{2m} \psi_i^e \frac{\partial \psi_j^e}{\partial r} + \frac{\hbar^2}{2} r \frac{\partial \psi_i^e}{\partial r} \left(\frac{1}{m} \frac{\partial \psi_j^e}{\partial r} \right) + \frac{\hbar^2 L^2}{2mr} \psi_i^e \psi_j^e + \frac{\hbar^2}{2} r \frac{\partial \psi_i^e}{\partial z} \left(\frac{1}{m} \frac{\partial \psi_j^e}{\partial z} \right) \right] dr dz \quad (23)$$

B_{ij}

$$= \int_{\Omega} [V - E] r \psi_i^e \psi_j^e dr dz \quad (24)$$

As a first choice the uniform mesh are used by the piecewise linear function three element, as shown in Figure(3) to represent the domain, to determine the element coefficient matrices A and B of Eq. (22).

To evaluation of the integral in Eq. (23) and Eq. (24), it is possible to obtain the closed form for the A and B matrices by carrying out the integrals in Eq. (23) and Eq. (24) exactly respectively. We consider element 1 as the typical element. Hence, the element coefficient A and B matrices are

Notes (1):

In the following example, the representative set of parameters were used for the calculations as:

For *InAs*, the energy gap $E_g = 0.42$ eV, $\Delta_1 = 0.38$ eV, $m_1(0) = 0.024 m_0$.

For *GaAs*, the energy gap $E_g = 1.52$ eV, $\Delta_1 = 0.34$ eV, $m_1(0) = 0.067 m_0$. The band offset parameter is taken as $V_0 = 0.55$ eV.

Example (1):

Consider the Nanoscal *InAs/GaAs*, quantum ring model, with using the above date to solve *InAs/GaAs*, nanostructures quantum ring.

In this example the FEM with piecewise linear function we used to solve equation (13).

Equation (13) is solved using MATLAB program at $n = 1296$. The results of numerical example give a good accuracy and efficiency of this method comparing with the results with FEM of linear triangular element and the maximum absolute error is less than 10^{-2} eV (as shown in Figure (4)).

3. Conclusions

The finite element method with using different base piecewise linear function are used for solving the nanoscale structures consisting of the *InAs/GaAs* quantum ring, and the spin-dependent on the Ben Daniel-Duke boundary conditions. The results of numerical example give a perfect accuracy and efficiency of this approach. The results of numerical example give a good accuracy and efficiency of this method in comparison with the results with FEM of linear triangular element
