### Abstract

Let  $R$  be commutative Ring , and let  $T$  be unitary left  $R$  – module .In this paper ,WAPP-quasi prime submodules are introduced as new generalization of Weakly quasi prime submodules , where proper submodule  $C$  of an  $R$ -module  $T$  is called WAPP –quasi prime submodule of  $T$ , if whenever  $0 \neq rst \in C$ , for  $r, s \in R, t \in T$ , implies that either  $r \in C + \text{soc}(T)$  or  $s \in C + \text{soc}(T)$  .Many examples of characterizations and basic properties are given . Furthermore several characterizations of WAPP-quasi prime submodules in the class of multiplication modules are established.

**Keywords:** Weakly quasi prime submodules ,WAPP-quasi prime submodules , Socle of modules ,  $Z$ -Regular modules , Projective modules .

### 1. Introduction

Throughout this paper , all rings are commutative with identity , and all modules are left unitary  $R$ -modules . Weakly quasi prim submodules was first introduced and studied in 2013 by [1] as a generalization of a weakly prime submodule , where proper submodule  $C$  of  $R$ -module  $T$  was called weakly prime submodule of  $C$  , if whenever  $0 \neq at \in C$  ,for  $a \in R, t \in T$ , implies that either  $t \in C$  or  $aT \subseteq C$  [2] , and a proper submodule  $C$  of  $R$ -module  $T$  is called weakly quasi prime submodule of  $T$  , if whenever  $0 \neq abt \in C$  , for  $a, b \in R, t \in T$ , implies that either  $at \in C$  or  $bt \in C$  . Recently many generalization of weakly quasi prime submodules were introduced see [3, 4, 5] . In this research we introduced another generalization of weakly quasi prime submodule , where proper submodule  $C$  of  $R$ -module  $T$  is called WAPP-quasi prime submodule of  $T$  , if whenever  $0 \neq abt \in C$  for  $a, b \in R, t \in T$  implies that either  $at \in C + \text{soc}(T)$  or  $bt \in C + \text{soc}(T)$ .  $\text{Soc}(T)$  is the socle of a module  $T$ , defined by the intersection of all essential submodule of  $T$  [6] , where a nonzero submodule  $A$  of an  $R$ -module  $T$  is called essential if  $A \cap B \neq (0)$  for each nonzero submodule  $B$  of  $T$  [6] . Recall that  $R$ -module  $T$  is

multiplication if every submodule  $C$  of  $T$  is of the form  $IT$  for some ideal  $I$  of  $R$ , in particular  $C=[C:R T] T$  [7]. Let  $A$  and  $B$  be a submodule of multiplication module  $T$  with  $A=IM$  and  $B=JT$  for some ideals  $I, J$  of  $R$ , then  $AB=IJT=IB$ . In particular  $AT=ITT=IT=A$ . Also for any  $t \in T$ ,  $At=A< t \rangle = It$  [8]. Recall that an  $R$ -module  $T$  is faithful, if  $\text{ann}(T)=(0)$  [7]. A  $R$ -module  $T$  is a projective if for any epimorphism  $f$  from  $R$ -module  $X$  into  $X'$  and for any homomorphism  $g$  from  $T$  in to  $X'$  there exists a homomorphism  $h$  from  $T$  in to  $X$  such that  $f \circ h=g$  [7]. Recall that an  $R$ -module  $T$  is a  $Z$ -regular, if for each  $t \in T$  there exists  $f \in T^*=\text{Hom}(T, R)$  such that  $t=f(t)t$  [10]

## 2. Basic Properties of WAPP-Quasi Prime Submodule

In this section, we introduced the definition of WAPP-quasi prime submodules and established some of its basic properties, characterization and examples.

### Definition(1)

A proper submodule  $C$  of an  $R$ -module  $T$  is called Weakly approximately quasi prime submodule of  $T$  (for short WAPP-quasi prime submodule), if whenever  $0 \neq abt \in C$ , for  $a, b \in R, t \in T$ , implies that either  $at \in C + \text{Soc}(T)$  or  $bt \in C + \text{Soc}(T)$ .

And an ideal  $J$  of ring  $R$  is called WAPP-quasi prime ideal of  $R$  if  $J$  is WAPP-quasi prime submodule of  $R$ -module  $T$ .

### Examples and Remarks(2)

1. The submodule  $C = \langle \bar{12} \rangle$  of the  $Z$ -module  $Z_{24}$  is a WAPP-quasi prime submodule of  $Z_{24}$ , since  $\text{Soc}(Z_{24}) = \langle \bar{4} \rangle$ , and for  $0 \neq abt \in \langle \bar{12} \rangle = \{ \bar{0}, \bar{12} \}$  for  $a, b \in Z, t \in Z_{24}$ , implies that either  $at \in \langle \bar{12} \rangle + \text{Soc}(Z_{24})$  or  $bt \in \langle \bar{12} \rangle + \text{Soc}(Z_{24})$ . That is either  $at \in \langle \bar{12} \rangle + \text{Soc}(Z_{24}) = \langle \bar{4} \rangle$  or  $bt \in \langle \bar{12} \rangle + \text{Soc}(Z_{24}) = \langle \bar{4} \rangle$  thus  $0 \neq 2.3. \bar{2} \in \langle \bar{12} \rangle$  for  $2, 3, \epsilon Z, \bar{2} \in Z_{24}$  implies that  $2. \bar{2} = \bar{4} \in \langle \bar{12} \rangle + \langle \bar{4} \rangle = \langle \bar{4} \rangle = \{ \bar{0}, \bar{4}, \bar{8}, \bar{12}, \bar{16}, \bar{20} \}$ .
2. The submodule  $12Z$  of the  $Z$ -module  $Z$  is not WAPP-quasi prime submodule, since  $\text{Soc}(Z) = (0)$  and whenever  $0 \neq 3.4.1 \in 12Z$ , for  $3, 4, 1 \in Z$ , implies that  $3.1 \notin 12Z + \text{Soc}(Z)$  and  $4.1 \notin 12Z + \text{Soc}(Z)$
3. It is clear that every weakly quasi prime submodule of an  $R$ -module  $T$  is WAPP-quasi prime but not conversely.

The following example explains that :

Consider the  $Z$ -module  $Z_{24}$ , and the submodule  $C = \langle \bar{6} \rangle = \{ \bar{0}, \bar{6}, \bar{12}, \bar{18} \}$ ,  $C$  is not weakly quasi prime submodule of  $Z_{24}$  since  $2.3. \bar{1} \in C = \langle \bar{6} \rangle$ , for  $2, 3 \in Z, \bar{1} \in Z_{24}$ , implies that  $2. \bar{1} = \bar{2} \notin \langle \bar{6} \rangle$  and  $3. \bar{1} = \bar{3} \notin \langle \bar{6} \rangle$ . But  $C$  is a WAPP-quasi prime submodule of  $Z_{24}$ , since  $\text{Soc}(Z_{24}) = \langle \bar{4} \rangle$ , and whenever  $0 \neq abt \in C = \langle \bar{6} \rangle = \{ \bar{0}, \bar{6}, \bar{12}, \bar{18} \}$  for  $a, b \in Z, t \in Z_{24}$  implies that either  $at \in C + \text{Soc}(Z_{24}) = \langle \bar{6} \rangle + \langle \bar{4} \rangle = \langle \bar{2} \rangle$  or  $bt \in C + \text{Soc}(Z_{24}) = \langle \bar{6} \rangle + \langle \bar{4} \rangle = \langle \bar{2} \rangle$ .

That is  $0 \neq 2.3. \bar{1} \in C$ , for  $2, 3 \in Z, \bar{1} \in Z_{24}$ , implies that  $2. \bar{1} \in C + \text{Soc}(Z_{24}) = \langle \bar{2} \rangle$ .

4. It is clear that ever weakly prime submodule of an  $R$ -module  $T$  is a WAAP-quasi prime but not conversely.

The following example explains that :

Consider the  $Z$ -module  $Z_{24}$  and the submodule  $C = \langle \overline{12} \rangle = \{0, \overline{12}\}$ . From (1),  $C$  is WAPP-quasi prime submodule of  $Z_{24}$ . But  $C$  is not weakly prime submodule of  $Z_{24}$ . Since if  $0 \neq 3 \cdot \overline{4} \in C$ , for  $3 \in Z$ ,  $\overline{4} \in Z_{24}$ , but  $\overline{4} \notin C$  and  $3 \notin [C : Z_{24}] = 6Z$

5. The residual of WAPP-quasi prime submodule  $C$  of an  $R$ -module  $T$  needs not to be WAPP-quasi prime ideal of  $R$ .

The following example explains that :

We have seen in(1) that the submodule  $C = \langle \overline{12} \rangle$  of the  $Z$  – module  $Z_{24}$  is a WAPP-quasi prime but  $[C :_Z Z_{24}] = \langle \overline{12} \rangle :_Z Z_{24} = 12Z$  is not WAPP-quasi prime ideal by (2).

6. The submodules  $PZ$  of a  $Z$ -module  $Z$  is a WAPP-quasi prime if and only if  $P$  is prime number
7. The intersection of two WAPP-quasi prime submodule of  $R$ -module,  $T$  need, not to be WAPP-quasi prime submodule of  $T$  for example:

The submodule  $2Z$  and  $5Z$  of the  $Z$ -module  $Z$  are WAPP-quasi prime submodule by (6).

But  $2Z \cap 5Z = 10Z$  is not WAPP-quasi prime submodule of the  $Z$  – module  $Z$ , since  $0 \neq 2 \cdot 5 \cdot 1 \in 10Z$ , for  $2, 5, 1 \in Z$  but  $2 \cdot 1 = 2 \notin 10Z + \text{Soc}(Z)$  and  $5 \cdot 1 = 5 \notin 10Z + \text{Soc}(Z)$

The following proposition are characterizations of WAPP-quasi prime submodules .

**Proposition(3)**

Let  $T$  be an  $R$  – modul and  $C$  be proper submodul of  $T$ , then  $C$  is WAPP – quasi prime sub modul of  $T$  if and only if , whenever  $0 \neq rsB \subseteq C$ , for  $r, s \in R$ ,  $B$  is submodul of  $T$ , implies that either  $rB \subseteq C + \text{Soc}(T)$  or  $sB \subseteq C + \text{Soc}(T)$ .

**Proof:**

( $\Rightarrow$ ) Assum that  $C$  is AWPP-quasi prime submodule of  $T$  and  $0 \neq rsB \subseteq C$ . For  $r, s \in R$ ,  $B$  is a submodule of  $T$ , with  $rB \not\subseteq C + \text{Soc}(T)$  and  $sB \not\subseteq C + \text{Soc}(T)$ , that is there exists a nonzero elements  $b_1, b_2 \in B$  such that  $rb_1 \notin C + \text{Soc}(T)$  and  $sb_2 \notin C + \text{Soc}(T)$ . Now  $0 \neq rsb_1 \in C$ , and  $C$  is WAPP-quasi prime submodule and  $rb_1 \notin C + \text{Soc}(T)$ , implies that  $sb_1 \in C + \text{Soc}(T)$ . Also  $0 \neq rsb_2 \in C$ , and  $C$  is a WAPP-quasi prime submodule of  $T$ , and  $sb_2 \notin C + \text{Soc}(T)$  .,implies that  $rb_2 \in C + \text{Soc}(T)$ . Again since  $0 \neq rs(b_1 + b_2) \in C$  and  $C$  is WAPP-quasi prime submodule of  $T$ , implies that either  $r(b_1 + b_2) \in C + \text{Soc}(T)$  or  $s(b_1 + b_2) \in C + \text{Soc}(T)$ . If  $r(b_1 + b_2) \in C + \text{Soc}(T)$ , that is  $rb_1 + rb_2 \in C + \text{Soc}(T)$ , and since  $rb_2 \in C + \text{Soc}(T)$ , it follows that  $rb_1 \in C + \text{Soc}(T)$  which is contradiction. If  $s(b_1 + b_2) \in C + \text{Soc}(T)$ , that is  $sb_1 + sb_2 \in C + \text{Soc}(T)$  and since  $sb_1 \in C + \text{Soc}(T)$ , it follows that  $sb_2 \in C + \text{Soc}(T)$  which is contradiction. Hence  $rB \subseteq C + \text{Soc}(T)$  or  $sB \subseteq C + \text{Soc}(T)$ .

( $\Leftarrow$ )

Let  $0 \neq rste \in C$ , for  $r, s \in R$ ,  $t \in T$ , it follows that  $0 \neq rs \langle t \rangle \subseteq C$ , so by hypothesis either  $r \langle t \rangle \subseteq C + \text{Soc}(T)$  or  $s \langle t \rangle \subseteq C + \text{Soc}(T)$ . That is either  $rte \in C + \text{Soc}(T)$  or  $ste \in C + \text{Soc}(T)$ . Hence  $C$  is WAPP – quasi prime submodul of  $T$ .

**Proposition(4)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodul of  $T$  if and only if whenever  $0 \neq IJB \subseteq C$ , for  $I, J$  are ideals of  $R$  and  $B$  is a submodule of  $T$ , implies that either  $IB \subseteq C + \text{Soc}(T)$  or  $JB \subseteq C + \text{Soc}(T)$ .

**Proof:**

( $\Rightarrow$ ) Assume that  $0 \neq IJB \subseteq C$ . For  $I, J$  are ideal of  $R$ ,  $B$  is a submodule of  $T$ , with  $IB \not\subseteq C + \text{Soc}(T)$  and  $JB \not\subseteq C + \text{Soc}(T)$ , so there exists a nonzero elements  $b_1, b_2 \in B$  and a nonzero elements  $r \in I, s \in J$  such that  $rb_1 \notin C + \text{Soc}(T)$  and  $sb_2 \notin C + \text{Soc}(T)$ . Now  $0 \neq rsb_1 \in C$ , and  $C$  is a WAPP-quasi prime submodule and  $rb_1 \notin C + \text{Soc}(T)$ , implies that  $sb_1 \in C + \text{Soc}(T)$ . Also  $0 \neq rsb_2 \in C$ , and  $C$  is a WAPP-quasi prime submodule of  $T$ , and  $sb_2 \notin C + \text{Soc}(T)$ , implies that  $rb_2 \in C + \text{Soc}(T)$ . Again  $0 \neq rs(b_1 + b_2) \in C$  and  $C$  is WAPP-quasi prime submodule of  $T$ , implies that either  $r(b_1 + b_2) \in C + \text{Soc}(T)$  or  $s(b_1 + b_2) \in C + \text{Soc}(T)$ . If  $r(b_1 + b_2) \in C + \text{Soc}(T)$ , that is  $rb_1 + rb_2 \in C + \text{Soc}(T)$ , and  $rb_2 \in C + \text{Soc}(T)$ , implies that  $rb_1 \in C + \text{Soc}(T)$  contradiction. If  $s(b_1 + b_2) \in C + \text{Soc}(T)$ , that is  $sb_1 + sb_2 \in C + \text{Soc}(T)$  and  $sb_1 \in C + \text{Soc}(T)$ , implies that  $sb_2 \in C + \text{Soc}(T)$  which is contradiction. Hence  $IB \subseteq C + \text{Soc}(T)$  or  $JB \subseteq C + \text{Soc}(T)$ .

( $\Leftarrow$ )

Suppose that  $0 \neq rst \in C$ , for  $r, s \in R, t \in T$ , that is  $0 \neq \langle r \rangle \langle s \rangle \langle t \rangle \subseteq C$ , so by our assumption either  $(r)(t) \subseteq C + \text{Soc}(T)$  or  $(s)(t) \subseteq C + \text{Soc}(T)$ . That is either  $rt \in C + \text{Soc}(T)$  or  $st \in C + \text{Soc}(T)$ . Hence  $C$  is WAPP-quasi prime submodule of  $T$ .

As a direct consequence of the above propositions, we get the following corollaries.

**Corollary(5)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodule of  $T$  iff whenever  $0 \neq rIt \subseteq C$ , for  $r \in R, I$  is an ideals of  $R$  and  $t \in T$ , implies that either  $rt \in C + \text{Soc}(T)$  or  $It \subseteq C + \text{Soc}(T)$ .

**Corollary(6)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodule of  $T$  iff whenever  $0 \neq IJt \subseteq C$ , for  $J, I$  is an ideals of  $R$  and  $t \in T$ , implies that either  $Jt \subseteq C + \text{Soc}(T)$  or  $It \subseteq C + \text{Soc}(T)$ .

**Corollary(7)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodul of  $T$  if and only if, for each  $r \in R$  and every ideal  $I$  of  $R$  and every submodule  $B$  of  $T$ , with  $0 \neq rIB \subseteq C$ , implies that either  $rB \subseteq C + \text{Soc}(T)$  or  $IB \subseteq C + \text{Soc}(T)$ .

**Proposition(8)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodule of  $T$  if and only if for each  $r, s \in R$ ,  $[C:rs] \subseteq [0:T rs] \cup [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ .

**Proof:**

( $\Rightarrow$ ) Let  $t \in [C:_T rs]$ , implies that  $rst \in C$ . If  $rst=0$ , then  $t \in [0:_T rs]$ , and hence  $t \in [0:_T rs] \cup [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ . Suppose that  $0 \neq rst \in C$  and since  $C$  is WAPP-quasi prime submodule of  $T$ , it follows that either  $rt \in C + Soc(T)$  or  $st \in C + Soc(T)$ , implies that either  $t \in [C + Soc(T):_T r]$  or  $t \in [C + Soc(T):_T s]$ . That is  $t \in [0:_T rs] \cup [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ . Hence,  $[C:_T rs] \subseteq [0:_T rs] \cup [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ .

( $\Leftarrow$ ) Assume that  $0 \neq rst \in C$ , for  $r, s \in R$ ,  $t \in T$ , implies that  $t \in [C:_T rs] \subseteq [0:_T rs] \cup [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ . But  $0 \neq rst$ , then  $t \notin [0:_T rs]$ , hence  $t \in [C + Soc(T):_T r] \cup [C + Soc(T):_T s]$ , it follows that  $rt \in C + Soc(T)$  or  $st \in C + Soc(T)$ . Hence,  $C$  is WAPP-quasi prime submodule of  $T$ .

**Proposition(9)**

Let  $T$  be  $R$  – modul and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quase priem submodule of  $T$  iff for every  $r \in R$ , and  $t \in T$  with  $rt \notin C + Soc(T)$ ,  $[C:_R rt] \subseteq [0:_R rt] \cup [C + Soc(T):_R t]$

**Proof:**

( $\Rightarrow$ ) Suppose that  $C$  is WAPP-quase , and let  $s \in [C:_R rt]$ , implies that  $rst \in C$ . If  $rst=0$  then  $s \in [0:_R r]$ , hence  $s \in [0:_R rt] \cup [C + Soc(T):_R t]$ . If  $0 \neq rst \in C$  and  $C$  is a WAPP-quasi prime submodule of  $T$  and  $rt \notin C + Soc(T)$ , then  $st \in C + Soc(T)$  that is  $s \in [C + Soc(T):_R t]$ . Hence  $s \in [0:_R rt] \cup [C + Soc(T):_R t]$ . Thus,  $[C:_R rt] \subseteq [0:_R rt] \cup [C + Soc(T):_R t]$ .

As a direct consequence of proposition (9) and proposition (3), we get the following corollary:

**Corollary(10)**

Let  $T$  be  $R$  – modul and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quase prim submodule of  $T$  iff for every  $r \in R$ , and any submodule  $B$  of  $T$  with  $rB \not\subseteq C + Soc(T)$ ,  $[C:_R rB] \subseteq [0:_R rB] \cup [C + Soc(T):_R B]$

As a direct consequence of proposition (9) and proposition (4) we get the following corollary.

**Corollary(11)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodule of  $T$  iff for every ideal  $I$  of  $R$ , and every submodule  $B$  of  $T$  with  $IB \not\subseteq C + Soc(T)$ ,  $[C:_R IB] \subseteq [0:_R IB] \cup [C + Soc(T):_R B]$ .

**Proposition(12)**

Let  $T$  be  $R$  – module and  $C$  be proper submodule of  $T$ . Then for every  $s, r \in R$ , and  $t \in T$ ,  $[C:{}_R rst] \subseteq [0:{}_R rst] \cup [C + Soc(T):{}_R rt] \cup [C + Soc(T):{}_R st]$ .

**Proof:**

Suppose that  $e \in [C:{}_R rst]$ , implies that  $rs(et) \in C$ . If  $rs(et) = 0$ , implies that  $e \in [0:{}_R rst]$  and hence  $e \in [0:{}_R rst] \cup [C + Soc(T):{}_R rt] \cup [C + Soc(T):{}_R st]$ . If  $rs(et) \neq 0$ , and  $C$  is a WAPP-quasi prime submodule of  $T$ , then either  $r(et) \in C + Soc(T)$  or  $s(et) \in C + Soc(T)$ . That is either  $e \in [C + Soc(T):{}_R rt]$  or  $e \in [C + Soc(T):{}_R st]$  thus  $e \in [0:{}_R rst] \cup [C + Soc(T):{}_R rt] \cup [C + Soc(T):{}_R st]$ . Therefore,  $[C:{}_R rst] \subseteq [0:{}_R rst] \cup [C + Soc(T):{}_R rt] \cup [C + Soc(T):{}_R st]$ .

The following are characterizations in the multiplication module .

**Proposition(13)**

Let  $T$  be multiplication  $R$ -module and  $C$  be proper submodule of  $T$ . Then  $C$  is a WAPP – quasi prime submodule of  $T$  iff  $0 \neq K_1 K_2 t \subseteq C$ , for some submodules  $K_1, K_2$  of  $T$ , and  $t \in T$  implies that either  $K_1 t \subseteq C + Soc(T)$  or  $K_2 t \subseteq C + Soc(T)$ .

**Proof:**

( $\Rightarrow$ ) Suppose that  $C$  is WAPP – quasi prime submodul of  $T$ , and  $0 \neq K_1 K_2 t \subseteq C$  for some submodules  $K_1, K_2$  of  $T$ , and  $t \in T$ . Since  $T$  is a multiplication, then  $K_1 = IT$  and  $K_2 = JT$  for some ideals  $I, J$  of  $R$ . Thus  $0 \neq K_1 K_2 t = IJt \subseteq C$ . Since  $C$  is a WAPP-quasi prime submodule of  $T$  then by corollary (6) either  $I t \subseteq C + Soc(T)$  or  $J t \subseteq C + Soc(T)$ . Hence either  $K_1 t \subseteq C + Soc(T)$  or  $K_2 t \subseteq C + Soc(T)$ .

( $\Leftarrow$ ) Assume that  $0 \neq IJt \subseteq C$ , for some ideals  $I, J$  of  $R, t \in T$ . That is  $0 \neq K_1 K_2 t \subseteq C$  for  $K_1 = IT$  and  $K_2 = JT$ . It follows that either  $K_1 t \subseteq C + Soc(T)$  or  $K_2 t \subseteq C + Soc(T)$ ; that is  $I t \subseteq C + Soc(T)$  or  $J t \subseteq C + Soc(T)$ . Hence  $C$  is a WAPP-quasi prime submodule of  $T$  by corollary(6).

**Proposition(14)**

Let  $T$  be multiplication  $R$ -module and  $C$  be proper submodule of  $T$ . Then  $C$  is WAPP – quasi prime submodule of  $T$  iff  $0 \neq K_1 K_2 H \subseteq C$ , for some submodules  $K_1, K_2$  and  $H$  of  $T$ , implies that either  $K_1 H \subseteq C + Soc(T)$  or  $K_2 H \subseteq C + Soc(T)$ .

**Proof:**

( $\Rightarrow$ ) Assume that  $0 \neq K_1 K_2 H \subseteq C$  for some submodules  $K_1, K_2$  and  $H$  of  $T$ . Since  $T$  is a multiplication, then  $K_1 = IT, K_2 = JT$  for some ideals  $I, J$  of  $R$  hence  $0 \neq K_1 K_2 H = IJH \subseteq C$ . But  $C$  is WAPP-quasi prime submodule of  $T$  then by proposition (4) either  $IH \subseteq C + Soc(T)$ . or  $JH \subseteq C + Soc(T)$ .. Hence either  $K_1 H \subseteq C + Soc(T)$ . or  $K_2 H \subseteq C + Soc(T)$ ..

( $\Leftarrow$ ) Let  $0 \neq IJH \subseteq C$ , where  $I, J$  are ideals of  $R$ , and  $H$  is a submodule of  $T$ . Since  $T$  is multiplication, then  $0 \neq IJH = K_1 K_2 H \subseteq C$ , hence by assumption either  $K_1 H \subseteq C + Soc(T)$  or  $K_2 H \subseteq C + Soc(T)$ . That is either  $IH \subseteq C + Soc(T)$  or  $JH \subseteq C + Soc(T)$ . Thus by proposition (4)  $C$  is WAPP-quasi prime submodul of  $T$ .

It is well – known that if  $T$  is  $Z$  – regular  $R$  – module , then  $\text{Soc}(T)=\text{Soc}(R)T$  [11;prop.(3-25)] .

**Proposition(15)**

Let  $T$  be  $Z$ -regular multiplication  $R$ -module and  $C$  be proper submodule of  $T$  . Then  $C$  is WAPP – quasi prime submodule of  $T$  iff  $[C:R T]$  is WAPP- quasi prime ideal of  $R$ .

proof:

( $\Rightarrow$ ) Suppose that  $C$  is WAPP – quasi prime submodule of  $T$  and let  $0 \neq aI \subseteq [C:R T]$  ,for  $a, b \in R$  ,  $I$  is an ideal of  $R$  .it follows that  $0 \neq ab(IT) \subseteq C$  . Since  $C$  is WAPP- quasi prime submodule of  $T$  , then by proposition(3) either  $aIT \subseteq C + \text{Soc}(T)$  or  $bIT \subseteq C + \text{Soc}(T)$ . But  $T$  is a  $Z$  –regular module , then  $\text{Soc}(T)=\text{Soc}(R)T$  ,and since  $T$  is multiplication , then  $C=[C:R T]T$  . Hence either  $aIT \subseteq [C:R T]T + \text{Soc}(R)T$  or  $bIT \subseteq [C:R T]T + \text{Soc}(R)T$ . Thus either  $aI \subseteq [C:R T] + \text{Soc}(R)$  or  $bI \subseteq [C:R T] + \text{Soc}(R)$  . Hence by proposition  $[C:R T]$  is a WAPP- quase priem ideal of  $R$ .

( $\Leftarrow$ ) Suppose that  $[C:R T]$  is a WAPP-quasi prime ideal of  $R$  , and  $0 \neq r s B \subseteq C$  , for  $r, s \in R$  , and  $B$  is a submodule of  $T$  . Since  $T$  is a multiplication , then  $B=IT$  ,for some ideal  $I$  of  $R$  ,that is  $0 \neq r s I T \subseteq C$ , it follows that  $0 \neq r s I \subseteq [C:R T]$  . For  $[C:R T]$  is a WAPP-quasi prime ideal , then by proposition(3) either  $rI \subseteq [C:R T] + \text{Soc}(R)$  or  $sI \subseteq [C:R T] + \text{Soc}(R)$  , it follows that either  $rIT \subseteq [C:R T]T + \text{Soc}(R)T$  or  $sIT \subseteq [C:R T]T + \text{Soc}(R)T$ . But  $T$  is a  $Z$ -regular  $\text{Soc}(T)=\text{Soc}(R)T$  and since  $T$  is a multiplication , then  $[C:R T]T=C$  .Thus either  $rB \subseteq C + \text{Soc}(T)$  or  $sB \subseteq C + \text{Soc}(T)$ . Hence by proposition (3)  $C$  is a WAPP-quasi prime submodule of  $T$ .

It is well-known that if an  $R$ -module  $T$  is projective , then  $\text{Soc}(T)=\text{Soc}(R)T$  [11;prop.(3-24)]

**Proposition(16)**

Let  $T$  be a projective multiplication  $R$ -module and  $C$  be a proper submodule of  $T$  . Then  $C$  is WAPP-quasi prime submodule of  $T$  if and only if  $[C:R T]$  is a WAPP- quasi prime ideal of  $R$ .

**Proof:**

( $\Rightarrow$ ) Let  $0 \neq r I J \subseteq [C:R T]$  ,for  $r \in R$  ,  $I, J$  are ideal of  $R$  .then  $0 \neq r I(JT) \subseteq C$  . Since  $C$  is WAPP- quasi prime submodule of  $T$  , then by corollary(7) either  $r(JT) \subseteq C + \text{Soc}(T)$  or  $I(JT) \subseteq C + \text{Soc}(T)$ . Now since  $T$  is a projective module , then  $\text{Soc}(T)=\text{Soc}(R)T$  ,and since  $T$  is multiplication , then  $C=[C:R T]T$  . Hence either  $r(JT) \subseteq [C:R T]T + \text{Soc}(R)T$  or  $I(JT) \subseteq [C:R T]T + \text{Soc}(R)T$ . It follows that , either  $rJ \subseteq [C:R T] + \text{Soc}(R)$  or  $IJ \subseteq [C:R T] + \text{Soc}(R)$  . Hence by corollary(7)  $[C:R T]$  is a WAPP-quasi prime ideal of  $R$ .

( $\Leftarrow$ ) Let  $0 \neq r I B \subseteq C$  , for  $r \in R$  ,  $I$  is an ideal in  $R$ , and  $B$  is submodule of. Since  $T$  is a multiplication , then  $B=JT$  ,for some ideal  $J$  of  $R$  .Thus  $0 \neq r I J T \subseteq C$ , implies that  $0 \neq r I J \subseteq [C:R T]$  . But  $[C:R T]$  is a WAPP-quasi prime ideal , then by corollary(7) either  $rJ \subseteq [C:R T] + \text{Soc}(R)$  or  $IJ \subseteq [C:R T] + \text{Soc}(R)$  , that is either  $rJT \subseteq [C:R T]T + \text{Soc}(R)T$  or  $IJT \subseteq [C:R T]T + \text{Soc}(R)T$ . Since  $T$  is a projective then  $\text{Soc}(T)=\text{Soc}(R)T$  and since  $T$  is a multiplication , then  $[C:R T]T=C$  .Thus

either  $rB \subseteq C + \text{Soc}(T)$  or  $IB \subseteq C + \text{Soc}(T)$ . Hence by corollary (7)  $C$  is a WAPP-quasi prime submodule of  $T$ .

We need to recall the following lemma before we introduce the next proposition .

**Lemma(17)[12, coro, of theo, (9)]**

Let  $T$  be a finitely generated multiplication  $R$ -module and  $I, J$  are ideals of  $R$  . Then  $IT \subseteq JT$  if and only if  $I \subseteq J + \text{ann}_R(T)$ .

**Proposition(18)**

Let  $T$  be a finitely generated multiplication  $Z$ -regular  $R$ -module and  $I$  is WAPP – quasi prime ideal of  $R$  with  $\text{ann}_R(T) \subseteq I$  . Then  $IT$  is an WAPP-quasi prime submodule of  $T$ .

**Proof:**

Let  $0 \neq I_1, I_2, B \subseteq IT$  , for  $I_1, I_2$  are is ideals of  $R$ , and  $B$  is submodule of  $T$ . Since  $T$  is a multiplication then  $B = JT$  for some ideal  $J$  of  $R$ . That is Let  $0 \neq I_1, I_2, (J T) \subseteq IT$ , it follows by lemma (17)  $0 \neq I_1, I_2, J \subseteq I + \text{ann}_R(T)$ . But  $\text{ann}_R(T) \subseteq I$ , implies that  $I + \text{ann}_R(T) = I$ . That is  $0 \neq I_1, I_2, J \subseteq I$ . But  $I$  is a WAPP-quasi prime ideal of  $R$  , then by proposition (4) either  $0 \neq I_1, J \subseteq I + \text{Soc}(R)$  or  $0 \neq I_2, J \subseteq I + \text{Soc}(R)$ . It follows that either  $0 \neq I_1, J T \subseteq IT + \text{Soc}(R)T$  or  $0 \neq I_2, J T \subseteq IT + \text{Soc}(R)T$ . But  $T$  is a  $Z$ -regular then  $\text{soc}(R)T = \text{Soc}(T)$ . Hence either  $0 \neq I_1, B \subseteq IT + \text{Soc}(T)$  or  $0 \neq I_2, B \subseteq IT + \text{Soc}(T)$ . Thus by proposition (4)  $IT$  is WAPP-quasi prime submodule of  $T$  .

**Proposition(19)**

Let  $T$  be a finitely generated multiplication projective  $R$ -module and  $I$  is a WAPP-quasi prime ideal of  $R$  with  $\text{ann}_R(T) \subseteq I$  . Then  $IT$  is WAPP-quasi prime submodule of  $T$ .

**Proof:**

Let  $0 \neq rI_1, B \subseteq IT$  , for  $r \in R, I_1$  is an ideal of  $R$ , and  $B$  is submodule of  $T$ . Since  $T$  is multiplication then  $B = JT$  for some ideal  $J$  of  $R$ . That is Let  $0 \neq rI_1, (J T) \subseteq IT$ , it follows by lemma (17)  $0 \neq rI_1, J \subseteq I + \text{ann}_R(T)$ . But  $\text{ann}_R(T) \subseteq I$ , implies that  $I + \text{ann}_R(T) = I$ . Hence  $0 \neq rI_1, J \subseteq I$ , and since  $I$  is WAPP-quasi prime ideal of  $R$  , then by corollary (7) either  $0 \neq rI_1, J \subseteq I + \text{Soc}(R)$  or  $0 \neq r, J \subseteq I + \text{Soc}(R)$ . That is either  $0 \neq rI_1, J T \subseteq IT + \text{Soc}(R)T$  or  $0 \neq r, J T \subseteq IT + \text{Soc}(R)T$ . But  $T$  is a projective then  $\text{soc}(R)T = \text{Soc}(T)$ . Thus either  $0 \neq rI_1, B \subseteq IT + \text{Soc}(T)$  or  $0 \neq r, B \subseteq IT + \text{Soc}(T)$ . Hence by corollary (7)  $IT$  is WAPP-quasi prime submodule of  $T$  .

It is well-known that cyclic  $R$ -module is multiplication [13], and since cyclic  $R$ -module is a finitely generated, we get the following corollaries:

**Corollary(20)**

Let  $T$  be a cyclic  $Z$ -regular  $R$ -module and  $I$  is WAPP-quasi prime ideal of  $R$  with  $\text{ann}_R(T) \subseteq I$  . Then  $IT$  is an WAPP-quasi prime submodule of  $T$ .

**Corollary(21)**

Let  $T$  be a cyclic projective  $R$ -module and  $I$  is an WAPP-quasi prime ideal of  $R$  with  $\text{ann}_R(T) \subseteq I$ . Then  $IT$  is an WAPP-quasi prim submodule of  $T$ .

It is well-known that if a submodule  $C$  of an  $R$ -module  $T$  is essential in  $T$ , then  $\text{Soc}(C) = \text{Soc}(T)$  [6, P.29].

**Proposition(22)**

Let  $T$  be  $R$ -module ,and  $A, B$  are submodules of  $T$  with  $A \not\subseteq B$  and  $B$  is an essential in  $T$ . If  $A$  is an WAPP-quasi prime submodule of  $T$ , then  $A$  is a WAPP-quasi prime submodule of  $B$ .

**Proof:**

Let  $0 \neq r, s, t \in A$ , for  $r, s \in R, t \in B$ , that is  $t \in T$ . Since  $A$  is a WAPP-quasi prime submodule of  $T$ , then either  $rt \in A + \text{Soc}(T)$  or  $st \in A + \text{Soc}(T)$ . But  $B$  is essential in  $T$ , then  $\text{soc}(B) = \text{Soc}(T)$ . That is either  $rt \in A + \text{Soc}(B)$  or  $st \in A + \text{Soc}(B)$ . Hence  $A$  is an WAPP-quasi prime submodule of  $B$ .

**Corollary(23)**

Let  $T$  be  $R$ -module ,and  $A, B$  are submodules of  $T$  with  $A \not\subseteq B$  and  $\text{Soc}(T) \subseteq \text{Soc}(B)$ . Then  $A$  is a WAPP-quasi prime submodule of  $B$ .

It well-known that if  $A$  is a submodule of an  $R$ -module  $T$ , then  $\text{Soc}(A) = A \cap \text{Soc}(T)$  [9, lema 2.3.15]

**Proposition(24)**

Let  $T$  be  $R$  – module ,and  $A, B$  are submodules of  $T$  with  $B$  not contain in  $A$ , and  $\text{Soc}(T) \subseteq B$ . If  $A$  is a WAPP-quasi prime submodule of  $T$ , then  $A \cap B$  is a WAPP-quasi prime submodule of  $B$ .

**Proof:**

It is clear that  $A \cap B$  is an proper submodule of  $B$ . Now ,let  $0 \neq r, s, t \in A \cap B$ , for  $r, s \in R, t \in B$ , implies that  $0 \neq r, s, t \in A$ , since  $A$  is a WAPP-quasi prime submodule of  $T$ , then either  $rt \in A + \text{Soc}(T)$  or  $st \in A + \text{Soc}(T)$ , hence either  $rt \in (A + \text{Soc}(T)) \cap B$  or  $st \in (A + \text{Soc}(T)) \cap B$ . Since  $\text{Soc}(T) \subseteq B$ , then by module law either  $rt \in (A \cap B) + (B \cap \text{Soc}(T))$  or  $st \in (A \cap B) + (B \cap \text{Soc}(T))$ . That is either  $rt \in (A \cap B) + \text{Soc}(B)$  or  $st \in (A \cap B) + \text{Soc}(B)$ . Thus  $A \cap B$  is a WAPP-quasi prime submodule of  $B$ .

It well-known that for each submodule  $A$  of an  $R$ -module  $T$ , then  $\text{Soc}(A) = A$ , then  $A \subseteq \text{Soc}(T)$  [9, theo.(9.1.4)(c)].

**Proposition(25)**

Let  $T$  be an  $R$  – module ,and  $A, B$  are submodules of  $T$  with  $B$  not contain in  $A$ , with  $\text{Soc}(A) = A$  and  $\text{soc}(B) = B$ . Then  $A \cap B$  is a WAPP-quasi prime sub module of  $T$ .

**Proof:**

Let  $0 \neq r, s \in L \subseteq A \cap B$ , for  $r, s \in R$ ,  $L$  is submodule of  $T$ , then  $0 \neq r, s \in L \subseteq A$ , and  $0 \neq r, s \in L \subseteq B$ . But both  $A, B$  are WAPP-quasi prime submodule of  $T$ , then either  $rL \subseteq A + \text{Soc}(T)$  or  $sL \subseteq A + \text{Soc}(T)$ , and  $rL \subseteq B + \text{Soc}(T)$  or  $sL \subseteq B + \text{Soc}(T)$ . But  $\text{Soc}(A) = A$  and  $\text{soc}(B) = B$ , then  $A \subseteq \text{Soc}(T)$  and  $B \subseteq \text{Soc}(T)$ , hence  $A + \text{Soc}(T) = \text{Soc}(T)$  and  $B + \text{Soc}(T) = \text{Soc}(T)$ ,  $A \cap B \subseteq \text{Soc}(T)$ , implies that  $A \cap B + \text{Soc}(T) = \text{Soc}(T)$ , so either  $rL \subseteq \text{Soc}(T) = A \cap B + \text{Soc}(T)$  or  $sL \subseteq \text{Soc}(T) = A \cap B + \text{Soc}(T)$ . Hence  $A \cap B$  is WAPP-quasi prime submodule of  $T$ .

**Proposition(26)**

Let  $f: T \rightarrow T'$  be an  $R$ -epimorphism, and  $C$  be an WAPP-quasi prime submodule of  $T$  with  $\text{ker}f \subseteq C$ . Then  $f(C)$  is WAPP-quasi prime submodule of  $T'$ .

**Proof:**

Let  $f: T \rightarrow T'$  be an  $R$ -epimorphism, and  $C$  be an WAPP-quasi prime submodule of  $T$  with  $\text{ker}f \subseteq C$ , let  $0 \neq r, s, t' \in f(C)$ , for  $r, s \in R, t' \in T'$ . Since  $f$  is onto, then  $f(t) = t'$ , for some  $t \in T$ , it follows that  $0 \neq r, s, f(t) \in f(C)$ ,  $0 \neq f(rst) \in f(C)$ , so there exists a nonzero  $x \in C$  such that,  $0 \neq f(rst) = f(x)$ . That is  $f(rst - x) = 0$ , implies that  $rst - x \in \text{ker}f \subseteq C$ , implies that  $0 \neq rst \in C$ . But  $C$  is a WAPP-quasi prime submodule of  $T$ , then either  $rt \in C + \text{Soc}(T)$  or  $s \in C + \text{Soc}(T)$ . That is either  $r f(t) \in f(C) + f(\text{Soc}(T)) \subseteq f(C) + \text{Soc}(T')$  or  $s f(t) \in f(C) + f(\text{Soc}(T)) \subseteq f(C) + \text{Soc}(T')$ . Thus either  $rt' \in f(C) + \text{Soc}(T')$  or  $st' \in f(C) + \text{Soc}(T')$ . Hence  $f(C)$  is an WAPP-quasi prime submodule of  $T'$ .

**Proposition(27)**

Let  $f: T \rightarrow T'$  be an  $R$ -epimorphism, and  $C$  be WAPP-quasi prime submodule of  $T'$ . Then  $f^{-1}(C)$  is an WAPP-quasi prime submodule of  $T$ .

**Prove:**

It is clearly that  $f^{-1}(C)$  is proper submodule of  $T$ . Let  $0 \neq r, s, t \in f^{-1}(C)$ , for  $r, s \in R, t \in T$ , it follows that then  $0 \neq r, s, f(t) \in C$ , but  $C$  is a WAPP-quasi prime submodule of  $T'$ , then either  $r f(t) \in C + \text{Soc}(T)$  or  $s f(t) \in C + \text{Soc}(T')$ . Thus either  $r t \in f^{-1}(C) + f^{-1}(\text{Soc}(T')) \subseteq f^{-1}(C) + \text{Soc}(T)$  or  $s t \in f^{-1}(C) + f^{-1}(\text{Soc}(T')) \subseteq f^{-1}(C) + \text{Soc}(T)$ . Hence  $f^{-1}(C)$  is WAPP-quasi prime submodule of  $T$ .

**Proposition(28)**

Let  $T$  be a  $Z$ -regular finitely generated multiplication  $R$  – module, and  $C$  be a proper submodule of  $T$ . Then the following statements are equivalent :

1.  $C$  is WAPP-quasi prime submodule of  $T$ .
2.  $[C:R T]$  is WAPP-quasi prime ideal of  $R$ .
3.  $C = IT$  for some WAPP-quasi prime ideal  $I$  of  $R$  with  $\text{ann}_R(T) \leq I$ .

**Poof:**

(1)  $\Rightarrow$  (2) Follows by proposition [15]

(2)  $\Rightarrow$  (3) Follows directly .

(3)  $\Rightarrow$  (2) Suppose that  $C=IT$  for some a some WAPP-quasi prime ideal of  $R$ . Since  $T$  is multiplication , then  $C=[C:{}_R T]T=IT$  and since  $M$  is finitely generated multiplication , then  $[C:{}_R T]= I+\text{ann}_R(T)$ . But  $\text{ann}_R(T)\subseteq I$  it follows that  $I+\text{ann}_R(T)=I$ . Thus  $[C:{}_R T]=I$  is a WAPP-quasi prime ideal of  $R$ . Hence  $[C:{}_R T]$  is WAPP-quasi prime ideal of  $R$ .

The following corollary is a direct consequence of proposition (28)

**Corollary(29)**

Let  $T$  be a cyclic  $Z$ -regular  $R$ -module , and  $C$  be proper submodule of  $T$  . Then the following statements are equipollent :

1.  $C$  is WAPP-quasi prime submodule of  $T$  .
2.  $[C:{}_R T]$  is WAPP-quasi prime ideal of  $R$  .
3.  $C=IT$  for some WAPP-quasi prime ideal  $I$  of  $R$  with  $\text{ann}_R(T)\subseteq I$  .

**Proposition(30)**

Let  $T$  be a finitely generated multiplication projective  $R$ -module , and  $C$  be a proper submodule of  $T$  . Then the following statements are equipollent :

1.  $C$  is a WAPP-quasi prime submodule of  $T$  .
2.  $[C:{}_R T]$  is WAPP-quasi prime ideal of  $R$  .
3.  $C=IT$  for some WAPP-quasi prime ideal  $I$  of  $R$  with  $\text{ann}_R(T)\subseteq I$  .

**Proof:**

(1)  $\Rightarrow$  (2) Follows by proposition (16)

(2)  $\Rightarrow$  (3) Follows directly.

(3)  $\Rightarrow$  (2) Follows as in proposition(28).

As a direct consequence of proposition (30), we get the following corollary :

**Corollary(31)**

Let  $T$  be cyclic projective  $R$  – module , and  $C$  be proper submodule of  $T$  , and  $C$  be a proper submodule of  $T$  . Then the following statements are equipollent :

1.  $C$  is WAPP-quasi prime submodule of  $T$  .
2.  $[C:{}_R T]$  is WAPP-quasi prime ideal of  $R$  .
3.  $C=IT$  for some WAPP-quasi prime ideal  $I$  of  $R$  with  $\text{ann}_R(T)\subseteq I$  .

It is well-known that if  $T$  is faithful multiplication  $R$  – module , then  $\text{Soc}(T)=\text{Soc}(R)T$  [7,CORO.(2.14)(1)].

**Proposition(32)**

Let  $T$  be a faithful multiplication  $R$  – module and  $C$  be a proper submodule of  $T$  . Then  $C$  is a WAPP-quasi prime submodule of  $T$  iff  $[C:{}_R T]$  is a WAPP- quasi prime ideal of  $R$ .

**Proof:**

( $\Rightarrow$ ) Let  $0 \neq IJk \subseteq [C:R T]$ , where  $I, J$  and  $k$  are ideals of  $R$ . then  $0 \neq IJ(kT) \subseteq C$ . Since  $C$  is WAPP- quasi prime submodule of  $T$ , then by proposition(4) either  $J(kT) \subseteq C + Soc(T)$  or  $J(kT) \subseteq C + Soc(T)$ . But  $T$  is a faithful multiplication, it follows that  $C = [C:R T]T$  and  $Soc(T) = Soc(R)T$ . Thus either  $I(KT) \subseteq [C:R T]T + Soc(R)T$  or  $J(KT) \subseteq [C:R T]T + Soc(R)T$ . Hence either  $I K \subseteq [C:R T] + Soc(R)$  or  $JK \subseteq [C:R T] + Soc(R)$ . Thus by proposition(4)  $[C:R T]$  is WAPP-quasi prime ideal of  $R$ .

( $\Leftarrow$ ) Let  $T 0 \neq abB \subseteq C$ , for  $a, b \in R$ , and  $B$  is submodule of  $T$ . Since  $T$  is multiplication, then  $B = JT$ , for some ideal  $J$  of  $R$ . Thus  $0 \neq abJT \subseteq C$ , it follows that  $0 \neq abJ \subseteq [C:R T]$ . But  $[C:R T]$  is WAPP-quasi prime ideal of  $R$ , then by proposition(3) either  $aJ \subseteq [C:R T] + Soc(R)$  or  $bJ \subseteq [C:R T] + Soc(R)$ , it follows that either  $aJT \subseteq [C:R T]T + Soc(R)T$  or  $bJT \subseteq [C:R T]T + Soc(R)T$ . But  $T$  is a faithful multiplication  $R$ -module then either  $aB \subseteq C + Soc(T)$  or  $bB \subseteq C + Soc(T)$ . Thus by proposition (3)  $C$  is a WAPP-quasi prime submodule of  $T$ .

The following corollary is a direct consequence of proposition(32)

**Corollary(33)**

Let  $T$  be a faithful cyclic  $R$ -module and  $C$  be a proper submodule of  $T$ . Then  $C$  is WAPP-quasi prime submodule of  $T$  if and only if  $[C:R T]$  is a WAPP- quasi prime ideal of  $R$ .

**3. Conclusion**

In this paper, we introduced and studied the concept WAPP-quasi prime submodule, and we established several examples, characterizations and basic properties of this concept. WAPP-quasi prime submodule is generalization of a Weakly quasi prime submodule so we give example for converse.

Among  $C$ , the main results of this paper are the following:

1. Proper submoduel  $C$  of  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff whenever  $(0) \neq rsB \subseteq C$ , for  $r, s \in R$ ,  $B$  is a submodule of  $T$ , implies that either  $rB \subseteq C + Soc(T)$  or  $sB \subseteq C + Soc(T)$
2. Proper submodule  $C$  of  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff whenever  $(0) \neq IJB \subseteq C$ , for  $I, J$  are ideals of  $R$ , and  $B$  is submodule of  $T$ , implies that either  $IB \subseteq C + Soc(T)$ . or  $JB \subseteq C + Soc(T)$ .
3. Proper submodule  $C$  of  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff for all  $r, s \in R$ ,  $[c:T rs] \subseteq [0:T rs] \cup [C:d_T r] \cup [C:T s]$

4. Proper submodule  $C$  of  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff for all  $r \in R, t \in T$  with  $rt \notin C + \text{Soc}(T)$ ,  $[C :_T rt] \subseteq [0 :_T rt] \cup [C + \text{Soc}(T) :_T t]$ .
5. Proper submodule  $C$  of multiplication  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff whenever  $(0) \neq K_1 K_2 t \subseteq C$ , for some submodules  $K_1, K_2$  of  $T$  and  $t \in T$ , implies that either  $K_1 t \subseteq C + \text{Soc}(T)$  or  $K_2 t \subseteq C + \text{Soc}(T)$
6. Proper submodule  $C$  of  $Z$ -regular multiplication  $R$ -module  $T$  is a WAPP-quasi prime submodule of  $T$  iff  $[C :_R T]$  is WAPP-quasi prime ideal of  $R$ .
7. Proper submodule  $C$  of projective multiplication  $R$ -module  $T$  is WAPP-quasi prime submodule of  $T$  iff  $[C :_R T]$  is WAPP-quasi prime ideal of  $R$ .
8. If  $T$  is a cyclic  $Z$ -regular  $R$ -module and  $I$  is WAPP-quasi prime ideal of  $R$  with  $\text{ann}_R(T) \subseteq I$ . Then  $IT$  is WAPP-quasi submodule of  $T$ .
